ECHO-EX

The Settlement Protocol

Classification: Established Sovereign Protocol — Architectural Baseline

Governance: MEDIFLO LLC · CA-202462418827 · Stanton, California

Function: Immutable anchoring & deterministic yield settlement

Ledger Basis: Solana SPL Token-2022 · 10,000 BPS fixed floor

CONFIDENTIAL · CONTROLLED DISTRIBUTION

— Contents

1 · The Blockchain as a Public Ledger **01**

2 · Anchoring a Verified Claim **02**

3 · SPL Token-2022 — The Receipt Standard **03**

4 · The 10,000 BPS Settlement Floor **04**

5 · A Transaction, Step by Step **05**

6 · Protocol EXITZ — The Circuit Breaker **06**

01 The Blockchain as a Public Ledger

Strip away every piece of crypto-jargon and a blockchain is one thing: an accounting ledger that no one can quietly edit after the fact.

Forget tokens, coins, and the noise of the market. Echo-Ex uses a blockchain for exactly one property — **immutability**. A traditional ledger lives on a server someone controls; entries can be changed, and you are asked to trust that they were not. A public blockchain ledger is replicated across an open network, and once an entry is written it cannot be altered without the whole network rejecting the change. That is the entire reason it is here: to make a verified carbon claim **permanent and tamper-evident**.

> *Imagine a ledger written in a book that thousands of people hold identical copies of, all at once. To change one line, you would have to change every copy simultaneously — impossible. That is what "anchoring to the chain" means: writing the entry into a book that can never be quietly rewritten.*

02 Anchoring a Verified Claim

Echo-Ex does not generate value. It **records** it. The value — a carbon-equivalent figure — arrives already verified from Aethexer, closed to ISO 14064, carrying its full provenance back to the public record. Echo-Ex's job begins only once that claim has passed verification.

ANCHOR, NOT MINT-FROM-NOTHING

The token Echo-Ex writes is a **cryptographic receipt of discovered telemetry** — a permanent marker that a specific, verified quantity of Energy Ghost was discovered, derived, and reconciled at a specific time. It represents the receipt of that data, not a claim of ownership over any third-party property. The chain remembers what the physics proved.

Verification is canonical and is referred to throughout the ecosystem as **Hash-Match**: the claim's computed SHA-256 fingerprint must reconcile exactly against its bound source record before anything is anchored. A claim that does not Hash-Match never reaches settlement.

03 SPL Token-2022 — The Receipt Standard

Echo-Ex is built on **Solana SPL Token-2022**, the extended token standard on the Solana network. The choice is deliberate and technical, not fashionable.

CAPABILITY	WHY ECHO-EX REQUIRES IT
Deterministic execution	Settlement logic runs identically every time — the split is enforced by the contract, not by a human operator.
Token-2022 extensions	Native hooks for transfer rules and metadata let the receipt carry its provenance and obey protocol constraints on-chain.
Low-latency finality	Anchoring completes in seconds, so the ledger reflects reality without a settlement backlog.
Public verifiability	Any party can inspect the anchored receipt against the chain — the audit is open by construction.

The receipt is minted deterministically by the contract once a claim has Hash-Matched. There is no discretionary issuance; the code is the sole authority over what is written.

04 The 10,000 BPS Settlement Floor

Every settlement in Echo-Ex is divided across a fixed basis-point floor. A basis point is one hundredth of one percent; **10,000 basis points is the whole — 100% — and that total is immutable.** No settlement can resolve to more or less than exactly 10,000 BPS. This is the protocol's sole hard-coded financial invariant, enforced by the contract on every single transaction.

70%
7,000 BPS
Primary Allocation

20%
2,000 BPS
Secondary Allocation

10%
1,000 BPS
Protocol Reserve

THE IMMUTABLE ARITHMETIC

7,000 + 2,000 + 1,000 = 10,000 BPS. The split always closes to the whole. If any leg were to change, the others must rebalance so the sum remains exactly 10,000 — the contract will not execute a settlement that violates this floor.

> *Think of a settled claim as a single whole pie, always cut into exactly one hundred equal hundredths of a percent — ten thousand of them. Seventy out of every hundred go to the primary leg, twenty to the*

secondary, ten held in reserve. The pie is never bigger or smaller than itself, and the knife is the smart contract, not a person.

05 A Transaction, Step by Step

1. **A verified claim arrives.** Aethexer hands Echo-Ex a carbon-equivalent figure, closed to ISO 14064, with its provenance bound.
2. **Hash-Match verification.** The claim's SHA-256 fingerprint is reconciled against its source record. No match, no settlement.
3. **Receipt anchored.** An SPL Token-2022 receipt is minted deterministically, permanently recording the verified discovery on the Solana ledger.
4. **Deterministic split applied.** The contract partitions the settlement across the fixed floor — 7,000 / 2,000 / 1,000 BPS — with the sum asserted to equal 10,000 before the transaction can finalize.
5. **Finality.** The transaction settles on-chain in seconds. The ledger now holds a permanent, publicly verifiable record of the discovery and its allocation.

06 Protocol EXITZ — The Circuit Breaker

Protocol EXITZ is the ultimate compliance safeguard — a server-side circuit breaker that governs whether settlement may proceed at all. It is non-monetized and operates silently at the backend; its sole function is control, not value.

ABSOLUTE COMPLIANCE, BY DESIGN

If any precondition of a sovereign, compliant settlement is not met — a failed Hash-Match, an integrity fault, a boundary condition outside the protocol's guarantees — EXITZ halts settlement before it is written. It is the mechanism that guarantees the chain only ever records claims that fully satisfy the protocol's constraints. The breaker defaults to **stop**: in any ambiguity, nothing settles.

This is what allows Echo-Ex to operate with sovereign authority rather than discretion. The rules are not enforced by trust in an operator; they are enforced by code that will refuse to proceed. EXITZ is the final assurance that every entry on the ledger is not merely recorded, but **compliant by construction.**
